

Procedure to Deploy Application to **Azure Cloud Services** via Docker Container

1. Prior to Containerization
 - a. Remove fixed baseURL in application UI
 - i. Import Location, LocationStrategy from @angular/common in app.component.ts
 - ii. Revise constructor to include Location and LocationStrategy
 - iii. Revise baseURL to this.location.path();
 - b. Create Package
 - i. Using Maven - package, create a package of the project
 - ii. Based on <packaging> information in pom.xml file), a .jar or .war file will be saved in the project's "target" directory
 - iii. Confirm .jar or .war file are located in the desired directory
2. Create Dockerfile
 - a. Using CLI commands, create Docker container
 - i. docker image build
 - ii. -t flag to name and tag file, format name:tag
 - iii. Specify destination directory
 - iv. Verify Docker image executes locally before pushing to Docker Hub
3. Upload Docker image to Docker Hub
 - a. Generate Access Token via Account Settings - Security
 - b. Create Repository
 - c. Push Docker image to Repository using "docker push" CLI command.
 - d. Make sure Docker Repository is Public via Visibility Settings
4. Set up Managed Environment and Deploy via Azure Cloud Services
 - a. Login to Azure portal OR Install Azure CLI
 - b. Create Resource
 - c. Create "container app"
 - i. Create and name new Resource Group
 - ii. Name the container app
 - iii. Deselect quickstart image
 - iv. Select Docker Hub as Image Source
 - v. Provide image and tag name
 - vi. Enable Ingress
 - vii. Accept traffic from anywhere
 - viii. Enter target port - 8080
 - ix. Preview settings entered and Create
 - x. Confirm deployment by clicking Application URL in the Overview
 - d. NOTE: Azure does not download the docker image. Azure requires continuous access to the docker image as a result.
